Adipic Acid and Benzoic Acid for Mink in the Growing Period
Tove N. Clausen, Peter Sandbøl & Carsten Hejlesen

Introduction
Urinary infections can be a big problem in mink farms. Especially in June and July, we find infections in the bladders of very fast growing male kits. They eat a lot of feed and thereby have a high excretion of waste products in the urine. Most often the problems stop when we start to use fish silage in the feed. The mineral acids from the fish silage are excreted in the urine, and thereby the urinary pH is lowered, crystals, if any, are dissolved and the growth of bacteria is restrained. I is recommended that the urine pH should be in the range between 6.0 and 6.6 (Case et al, 1995).
From the time when the kits start to eat and until silage is added to the feed, there might be a problem with bladder infections.
Addition of ammonium chloride lowers the urine pH, but using it daily in too high amounts might reduce feed intake (Clausen, 2000).
Adding other kinds of acids that do not influence the taste of the feed in a negative way, could be interesting.
A pilot study in the N-balance stable showed, that addition of adipic acid or benzoic acid might be a possibility (Lisbjerg, 2005).

Methods
To this investigation we used three groups of siblings with 55 black male mink kits in each group.
The investigation started on July 11 and one group (CON) got control feed, one group (ADP) got feed added 0.34 % adipic acid and the last group (BEN) got feed added 0.1 % benzoic acid.
The kits were weighed on July 8, August 1, September 1, October 6 and at pelting.
Urine samples (spot-urine) were taken on July 7, July 27, August 30, October 4 and December 12.

Results and discussion
The weight of the male mink kits are seen in figure 1. The ADP group had a higher weight gain than the other groups from July until pelting. Also the length of the skins were better in this group. In colour, quality, density and silky skin there were no differences. However there was a difference in the number of skins with metallic, so that CON, ADP and BEN had 13.5, 6 and 0 % skins with metallic respectively.

Some of the results of the blood samples are shown in table 2. There were no differences in the acid base balance between groups (not shown), and all values were within the normal range. Addition of these acids to the feed during the growing period had no negative effect on the acid-base balance of the kits.

Table 2. Results of blood samples (15 per group) taken at pelting. Hct is hematocrit, Hb is hemoglobin, Na is natrium, K is kalium.

There were no differences between groups in the liver fat content or the relative liver weight.

Conclusion
Addition of adipic acid 0.34% or benzoic acid 0.1% in the feed for mink kits during the growing period, did not influence acid-base balance of the animals at pelting. Adipic acid gave longer skins than control kits without addition of acid and kits with benzoic acid in their feed. Compared to the control group adipic acid lowered the urine pH and benzoic acid only caused a limited, but not lasting lowering of the urine pH. In the adipic group there were most dead kits. Further investigations of adipic acid in the early growth period, is necessary before the product is recommended for use.
